Project description:

Chronic lymphocytic leukemia (CLL) is characterized by the accumulation of clonal mature B-cells in the peripheral blood and lymphoid organs; CLL cells are strongly dependent on B-cell receptor signaling molecules as witnessed by the recent approval of drugs targeting different BCR-associated kinases (1). Nonetheless, BCR stimulation leads to the activation of distinct transcription factors including NFAT whose constitutive activation has been reported in CLL as well as other B-cell malignancies (1,2). **NFAT family** includes five members that share sequence similarity and that act as transcription factors; NFAT1-4 are calcium dependent while NFAT5 is regulated by osmotic stress (1). Targeting NFAT in CLL has been recently proposed as a novel potential therapeutic approach based on preclinical data using a specific peptide that blocks calcium dependent NFATs activation and translocation into the nucleus; the addition of the VIVIT peptide *in vitro* induced apoptosis of leukemic cells, and reduced tumor growth *in vivo* in mouse models (2). The aim of this PhD project is to functionally dissect the **signaling framework of different NFAT** family members, and to optimize NFAT pharmacological targeting in CLL.

To achieve this, we will:

Perform CUT&Tag followed by RNA-seq analyses to identify and characterize the target genes of different NFAT family members in normal and leukemic cells. These studies will drive the characterization of novel potential biomarkers of NFAT activation/inhibition.

Test different nanconstructs targeting NFATs activation by using preclinical models of CLL including primary cells, cell lines and mouse models (2,3).

Skills to be acquired by the student:

Cellular and molecular biology techniques including CUT&Tag and single cell RNA-seq.

Independent critical thinking; experimental planning and design; data analysis and data/progress reports; seminar presentations to the scientific community.
